## Current Mode Boost Controller

## General Description

The RT8525D is a wide input operating voltage range step up controller. High voltage output and large output current are feasible by using an external N-MOSFET. The RT8525D input operating range is from 4.5 V to 25 V .

The RT8525D is an optimized design for wide output voltage range applications. The output voltage of the RT8525D can be adjusted by the FB pin.

## Ordering Information

RT8525D $\square \square$
Package Type
QW : WDFN-12L 3x3 (W-Type)
(Exposed Pad-Option 2)
Lead Plating System
G: Green (Halogen Free and Pb Free)

## Note :

Richtek products are :

- RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- Suitable for use in SnPb or Pb -free soldering processes.

## Marking Information

OF=YM

DNN $\quad$| OF=: Product Code |
| :--- |
| YMDNN : Date Code |

## Features

- VIN Range : 4.5V to 25V
- Programmable Soft-Start Time
- Programmable Boost SW Frequency from 50kHz to 600kHz
- Output Over Voltage Protection
- Output Under Voltage Protection
- 12-Lead WDFN Package
- RoHS Compliant and Halogen Free

## Applications

- LCD TV, Monitor Display Backlight
- LEDDriver Application
- High Current High Output Voltage DC/DC Converters
- High Input Voltage DC/DC Converters

## Pin Configurations

WDFN-12L 3x3

## Simplified Application Circuit

Functional Pin Description

| Pin No. | Pin Name | Pin Function |
| :---: | :--- | :--- |
| 1 | VDC | Output of Internal Pre-Regulator. |
| 2 | VIN | IC Power Supply. |
| 3 | COMP | Compensation for Error Amplifier. Connect a compensation network to ground. |
| 4 | SS | External Capacitor to Adjust Soft-Start Time. |
| 5 | FSW | Frequency Adjust Pin. This pin allows setting the switching frequency with a <br> resistor from 50kHz to 600kHz. |
| 6 | FAULT | Open Drain Output for Fault Detection. |
| 7 | FB | Feedback to Error Amplifier Input. |
| 8 | OVP | Sense Output Voltage for Over Voltage Protection and Under Voltage Protection. |
| 9 | ISW | External MOSFET Switch Current Sense Pin. Connect the current sense resistor <br> between the external N-MOSFET switch and ground. |
| 10, | GND | Ground of Boost Controller. The exposed pad must be soldered to a large PCB <br> and connected to GND for maximum power dissipation. |
| 11 | DRV | Drive Output for the N-MOSFET. |
| 12 | EN | Chip Enable (Active High). |

## Function Block Diagram

## Operation

The RT8525D is a wide input operating voltage range and current mode step up controller. High voltage output and large output current are feasible by using an external N MOSFET.

The error amplifier EA adjusts COMP voltage by comparing the feedback signal from the output voltage with the internal 1.25 V reference.

## Fault Protection

The protection functions include output over voltage, output under voltage, over temperature protection. The $\overline{\mathrm{FAULT}}$ pin will be pulled low once a protection is triggered, and a suitable pulled-high $R_{F L T}$ is required. The detail description can refer to the Figure 2. Fault Protection Function Block.

## Blanking

N-MOSFET current is measured by external RS. The slope compensator works together with sensing voltage of $\mathrm{R}_{\text {SENSE }}$ to the ISW pin. There is need blanking time to avoid noise and parasitism effect.

Note 1. Stresses beyond those listed "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.
Note 2. $\theta_{\mathrm{JA}}$ is measured at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ on a high effective thermal conductivity four-layer test board per JEDEC 51-7. $\theta_{\mathrm{Jc}}$ is measured at the exposed pad of the package.

Note 3. Devices are ESD sensitive. Handling precaution is recommended.
Note 4. The device is not guaranteed to function outside its operating conditions..

## Applications Information

The RT8525D is a wide input operating voltage range step up controller. High voltage output and large output current are feasible by using an external N-MOSFET. The protection functions include output over voltage, output under voltage, over temperature and current limiting protection.

## Boost Output Voltage Setting

The regulated output voltage is set by an external resistor divider according to the following equation :
$V_{\text {OUT }}=V_{F B} \times\left(1+\frac{R_{F B 1}}{R_{F B 2}}\right)$, where $V_{F B}=1.25 \mathrm{~V}$ (typ.)
The recommended value of $R_{\text {FB2 }}$ should be at least $1 \mathrm{k} \Omega$ for saving sacrificing. Moreover, placing the resistor divider as close as possible to the chip can reduce noise sensitivity.

## Boost Switching Frequency

The RT8525D boost driver switching frequency is able to be adjusted by a resistor $\mathrm{R}_{\mathrm{Sw}}$ ranging from $18 \mathrm{k} \Omega$ to $220 \mathrm{k} \Omega$. The following figure illustrates the corresponding switching frequency within the resistor range.

Figure 1. Boost Switching Frequency

## Boost Loop Compensation

The voltage feedback loop can be compensated by an external compensation network consisted of $\mathrm{R}_{\mathrm{C}}, \mathrm{C}_{\mathrm{C} 1}$ and $\mathrm{C}_{\mathrm{C} 2}$. Choose $\mathrm{R}_{\mathrm{C}}$ to set high frequency gain for fast
transient response. Select $\mathrm{C}_{\mathrm{C} 1}$ and $\mathrm{C}_{\mathrm{C} 2}$ to set the zero and pole to maintain loop stability. A typical compensation for the RT8525D is choosing $3 k \Omega$ for $R_{C}$ and $27 n F$ for $C_{C 1}$.

## Soft-Start

The soft-start of the RT8525D can be achieved by connecting a capacitor from the SS pin to GND. The builtin soft-start circuit reduces the start-up current spike and output voltage overshoot. The external capacitor charged by an internal $4 \mu \mathrm{~A}$ constant charging current determines the soft-start time. The SS pin limits the rising rate of the COMP pin voltage and thereby limits the peak switch current. The soft-start interval is set by the soft-start capacitor according to the following equation :
$\mathrm{tss} \cong \mathrm{CSS} \times 5 \times 10^{5}$
A typical value for the soft-start capacitor is $0.33 \mu \mathrm{~F}$. The soft-start capacitor is discharged when EN voltage falls below its threshold after shutdown delay or UVLO occurs.

## Slope Compensation and Current Limiting

A slope compensation is applied to avoid sub-harmonic oscillation in current-mode control. The slope compensation voltage is generated by the internal ramp current flow through a slope compensation resistor RsLP. The inductor current is sensed by the sensing resistor Rs. Both of them are added and presented on the ISW pin. The internal ramp current is rising linearly form zero at the beginning of each switching cycle to $50 \mu \mathrm{~A}$ in maximum on-time of each cycle. The slope compensation resistor RSLP can be calculated by the following equation :
$R_{\text {SLP }}>\frac{\left(\text { VOUT }-\mathrm{V}_{\text {IN }}\right) \times \mathrm{R}_{\text {S }}}{2 \times \mathrm{L} \times 50 \mu \times \mathrm{f}_{\text {SW }}}$
where $R_{S}$ is current sensing resistor, $L$ is inductor value, and $f_{s w}$ is boost switching frequency.

The current flow through inductor during charging period is detected by a sensing resistor $\mathrm{R}_{\mathrm{s}}$. Besides, the slope compensation voltage also attributes magnitude to ISW. As the voltage at the ISW pin is over 0.4 V , the DRV will be pulled low and turn off the external N-MOSFET. So that the inductor will be forced to leave charging stage and enter discharging stage to prevent over current. The current limiting can be calculated by the following equation:
$R_{S}<\frac{0.4-D_{M A X} \times R_{\text {sLP }} \times 50 \mu}{I_{L}, \text { PK }}$
where $I_{L, P K}$ is peak inductor current, and $\mathrm{D}_{\text {MAX }}$ is maximum duty.

## Output Over Voltage Protection

The output voltage can be clamped at the voltage level determined by the following equation :
$V_{\text {OUT (OVP) }}=V_{\text {OVP }} \times\left(1+\frac{\text { RoVP1 }}{\text { RoVP2 }}\right)$,
where $\mathrm{V}_{\mathrm{ovp}}=2.5 \mathrm{~V}$ (typ.)
where Rovp1 and Rovp2 are the voltage divider connected to the OVP pin.

## Fault Protection

The FAULT pin will be pulled low once a protection is triggered, and a suitable pulled-high $R_{\text {FLT }}$ is required. The suggested $R_{\text {FL }}$ is $100 \mathrm{k} \Omega$ if the pulled-high voltage was 12 V . The following figure illustrates the fault protection function block. If one of the OUVP and OTP occurs, the switch 1 will be turned on, and the voltage at node $A$ will be under 0.25 V . Then the protection function will perform
action 2 to turn off the driver. When protection function is released, the RT8525D will re-start.

On the other hand, if the triggered protection is OVP, the voltage at node A will be decided by voltage divider composed of $\mathrm{R}_{\text {FLT }}$ and the internal $8 \mathrm{k} \Omega$ resistor. This voltage must be designed between 0.25 V and 1.25 V by choosing $\mathrm{R}_{\text {FLT }}$ appropriately. Once the OVP turns on the Switch 2, the divided FAULT voltage will activate action 1 to turn off the driver without resetting soft-start. Therefore, when protection function OVP is released, the RT8525D will be in normal operation.

## Power MOSFET Selection

For the applications operating at high output voltage, switching losses dominate the overall power loss. Therefore, the power N-MOSFET switch is typically chosen for drain voltage, VDS, rating and low gate charge. Consideration of switch on-resistance $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ is usually secondary. The VDC regulator in the RT8525D has a fixed output current limit to protect the IC and provide 12VDRV voltage for N -MOSFET switch gate driver.

Figure 2. Fault Protection Function Block

## Inductor Selection

The boundary value of the inductance $L$ between Discontinuous Conduction Mode (DCM) and Continuous Conduction Mode (CCM) can be approximated by the following equation :
$\mathrm{L}=\frac{\mathrm{D} \times(1-\mathrm{D})^{2} \times \mathrm{V}_{\text {OUT }}}{2 \times \mathrm{fS}_{\text {SW }} \times \text { louT }}$
where
$V_{\text {Out }}$ is the maximum output voltage,
$\mathrm{V}_{\text {IN }}$ is the minimum input voltage,
fsw is the operating frequency,
lout is the sum of current from all LED strings,
and D is the duty cycle calculated by the following equation:
$D=\frac{V_{\text {OUT }}-V_{\text {IN }}}{V_{\text {OUT }}}$
The boost converter operates in DCM over the entire input voltage range if the inductor value is less than the boundary value L . With an inductance greater than L , the converter operates in CCM at the minimum input voltage and may transit to DCM at higher voltages. The inductor must be selected with a saturated current rating greater than the peak current provided by the following equation :
LLPK $=\frac{\mathrm{V}_{\text {OUT }} \times \text { lout }}{\eta \times \mathrm{V}_{\text {IN }}}+\frac{\mathrm{VIN} \times \mathrm{D} \times \mathrm{T}}{2 \times \mathrm{L}}$
where $\eta$ is the efficiency of the power converter.

## Diode Selection

Schottky diodes are recommended for most applications because of their fast recovery time and low forward voltage. The power dissipation, reverse voltage rating and pulsating peak current are the important parameters for Schottky diode selection. Make sure that the diode's peak current rating exceeds ILPK, and $^{\text {reverse voltage rating exceeds }}$ the maximum output voltage.

## Capacitor Selection

Output ripple voltage is an important index for estimating the performance. This portion consists of two parts, one is the product of input current and ESR of output capacitor, another part is formed by charging and discharging process of output capacitor. Refer to figure 3, evaluate $\Delta \mathrm{V}_{\text {out1 }}$ by ideal energy equalization. According to the definition of $Q$, the $Q$ value can be calculated as following equation :
$Q=\frac{1}{2} \times\left[\left(\mathrm{IIN}_{\mathrm{N}}+\frac{1}{2} \Delta \mathrm{IL}-\right.\right.$ lOUT $)+\left(\mathrm{IIN}_{\mathrm{N}}-\frac{1}{2} \Delta \mathrm{IL}-\right.$ IOUT $\left.)\right] \times \frac{\mathrm{V}_{\text {IN }}}{\mathrm{V}_{\text {OUT }}}$ $\times \frac{1}{\text { fSW }}=$ COUT $\times \Delta$ V OUT 1
where $f_{S W}$ is the switching frequency, and $\Delta I_{\mathrm{L}}$ is the inductor ripple current. Move Cout to the left side to estimate the value of $\Delta \mathrm{V}_{\text {OUT1 }}$ as the following equation :
$\Delta$ VOUT1 $=\frac{\mathrm{D} \times \text { lout }}{\eta \times \text { COUT } \times \text { fsW }}$
Finally, by taking ESR into consideration, the overall output ripple voltage can be determined as the following equation :
$\Delta$ VOUT $=\operatorname{lin} \times E S R+\frac{D \times \text { loUT }}{\eta \times \text { COUT } \times \text { fSW }}$

Figure 3. The Output Ripple Voltage without the Contribution of ESR

## Thermal Considerations

For continuous operation, do not exceed absolute maximum junction temperature. The maximum power dissipation depends on the thermal resistance of the IC package, PCB layout, rate of surrounding airflow, and difference between junction and ambient temperature. The maximum power dissipation can be calculated by the following formula :
$P_{D(\text { MAX })}=\left(T_{J(M A X)}-T_{A}\right) / \theta_{J A}$
where $T_{J(M A X)}$ is the maximum junction temperature, $T_{A}$ is the ambient temperature, and $\theta_{\mathrm{JA}}$ is the junction to ambient thermal resistance.

For recommended operating condition specifications, the maximum junction temperature is $125^{\circ} \mathrm{C}$. The junction to ambient thermal resistance, $\theta_{\mathrm{JA}}$, is layout dependent. For WDFN-12L $3 \times 3$ package, the thermal resistance, $\theta_{\mathrm{JA}}$, is $60^{\circ} \mathrm{C} / \mathrm{W}$ on a standard JEDEC 51-7 four-layer thermal test board. The maximum power dissipation at $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$ can be calculated by the following formula :
$P_{D(\operatorname{MAX})}=\left(125^{\circ} \mathrm{C}-25^{\circ} \mathrm{C}\right) /\left(60^{\circ} \mathrm{C} / \mathrm{W}\right)=1.667 \mathrm{~W}$ for
WDFN-12L 3x3 package
The maximum power dissipation depends on the operating ambient temperature for fixed $\mathrm{T}_{\mathrm{J}(\mathrm{MAX})}$ and thermal
resistance, $\theta_{\mathrm{JA}}$. The derating curve in Figure 4 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

Figure 4. Derating Curve of Maximum Power Dissipation

## Layout Considerations

PCB layout is very important for designing switching power converter circuits. The following layout guides should be strictly followed for best performance of the RT8525D.

- The power components $L_{1}, D_{1}, C_{I N}, C_{\text {out }}, M 1$ and $R_{S}$ must be placed as close as possible to reduce current loop. The PCB trace between power components must be as short and wide as possible.
- Place components $R_{\text {FB1 }}$ and $R_{\text {FB2 }}$ close to IC as possible. The trace should be kept away from the power loops and shielded with a ground trace to prevent any noise coupling.
- The compensation circuit should be kept away from the power loops and should be shielded with a ground trace to prevent any noise coupling. Place the compensation components to the COMP pin as close as possible, no matter the compensation is $R_{\mathrm{C}}, \mathrm{C}_{\mathrm{C} 1}$ or $\mathrm{C}_{\mathrm{C} 2}$.

The feedback voltage divider resistors must near the feedback pin. The divider center trace must be shorter and avoid the trace near any switching nodes.
